## ACKNOWLEDGEMENTS

The authors are grateful to the Agricultural Data Center for assistance in summarizing the results presented in this progress report. Also, acknowledgements are made to the following people who helped conduct this year's performance test.

Dr. Morris Bitzer, Extension Specialist in Grain Crops, Lexington  
Dr. John R. Hartman and Dr. Richard E. Stuckey, Department of Plant Pathology, Lexington  
Dr. James Herbek, Extension Specialist in Grain Crops, Research and Education Center, Princeton  
Donnie Davis, Superintendent, Research and Education Center, Princeton  
George A. Armstrong, Superintendent, Robinson Substation, Quicksand (Retired)  
Gordon Henshaw, Extension Agent, Bardwell  
William Hendrick, Extension Agent, Henderson  
Rodney Haines, Extension Agent, Russellville  
John Jarvis, Extension Agent, Frankfort  
Gene Brown, Extension Agent, Morganfield  
Roy Catlett, Extension Agent, Shelbyville  
Mason Morrison, Superintendent, Robinson Substation, Quicksand  
Charles May, Extension Agent, Hindman (Formerly corn project technician)

# 1986 Kentucky Hybrid Corn Performance Test

C. G. Poneleit and K. O. Evans

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

## PRESENTATION OF DATA

Complete 1986 data are presented for the tests at each location. Two- and three-year averages for yield are included in each of the single location tables when available. Readers are encouraged to consider these multiple year averages and the averages over locations (Tables 11, 12, and 13) since these are better estimates of a hybrid's yield ability than data gathered at one location in one year. The two- and three-year summary tables (Tables 12 and 13) contain data only from those locations where appropriate data are available for 1984, 1985, or 1986.

Comparisons between yields or other characteristics of any two or more hybrids should be made only with data from one table at a time. The testing

procedures do not provide a suitable comparison between a hybrid grown at one location and another grown at a different location.

## TESTING PROCEDURE

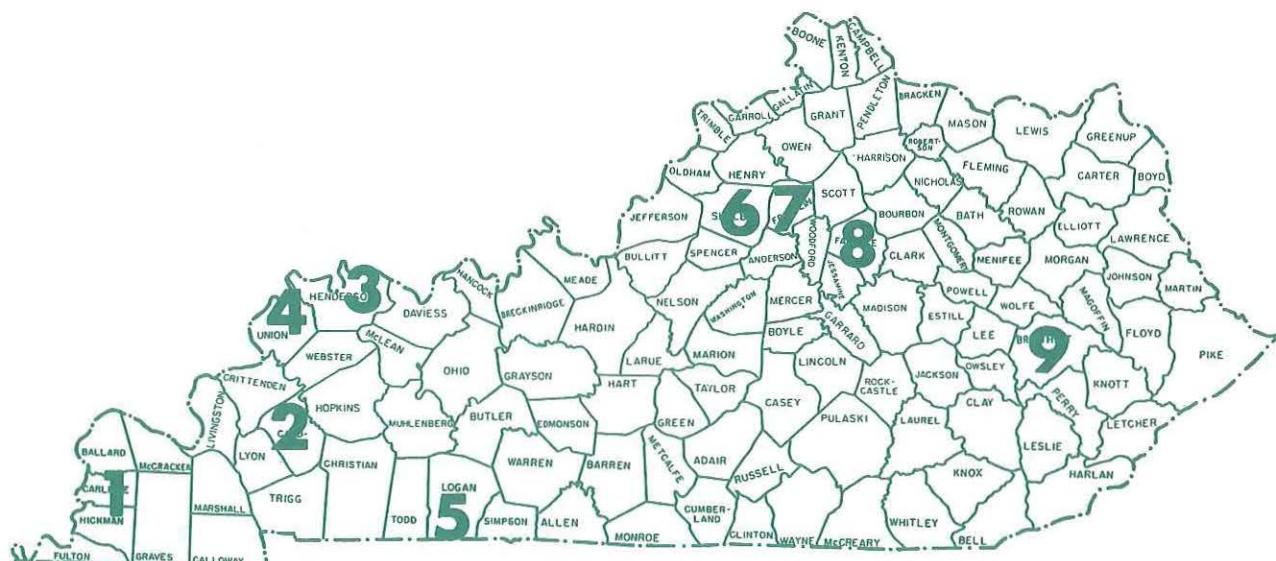

### Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 1987. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company.

Those hybrids grown in the corn virus tests are indicated in column 2 of Table 2. The hybrid corn companies were asked to nominate those hybrids known to have virus resistance for inclusion in the virus test.

### Location of Tests

The map below shows the location for each test. The non-virus test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity. The Henderson and Frankfort

Locations of the 1986 Kentucky Hybrid Corn Performance Test

sites were chosen specifically for the presence of corn virus in diverse areas of the state and may represent differences in virus populations.

### Cultural Practices

The seedbeds at each location except Shelbyville and Bardwell were prepared by conventional tillage methods. Fertilizer was applied as indicated by soil tests. The test at Shelbyville was planted in a wheat/soybean residue and at Bardwell in a corn/wheat residue using recommended no-tillage practices. All test areas were treated with herbicide and supplemented by post-emergence cultivation and/or herbicide when necessary. Except for the virus tests, Furadan was applied in the row at planting. Table 3 shows the specific cultural treatment for each location. The virus tests received Dyfonate as a surface applied insecticide at planting to control corn rootworms.

### Experimental Design

Each hybrid was grown in three separate plots at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site while 2-year and 3-year means are averages of six and nine replications, respectively. An 11 x 12 lattice design was used at each non-virus location, and a 7 x 8 lattice design was used at the virus locations.

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) quoted at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yielding ability. "N.S." in the tables indicates that no statistically significant differences were determined. The LSD is calculated for an  $\alpha$  level of 0.10.

### Planting

All plots were planted with a two-row, no-till planter modified for small plot work. The planter

boxes were replaced by special planting cones which allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 36 inches apart and 22 feet long. Each conventional tillage test was planted at the rate of 23,760 kernels per acre. The no-till test at Shelbyville was planted at a rate of 25,740 kernels per acre. Final stands were expected to be between 20,000 and 22,000 plants per acre if average stand losses occurred.

### Harvesting

All plots were harvested with a modified two-row self-propelled corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot were measured with an electronic scale and moisture meter mounted on the combine. Data from most test locations was temporarily stored in a portable data logging device prior to transfer to a computer at Lexington. Yields were calculated and adjusted to No. 2 at 15.5% moisture. Dropped ears were not gleaned from the plots. The total number of plants and lodged plants were recorded immediately prior to harvest.

### Corn Virus

Two corn virus diseases occur in Kentucky: maize dwarf mosaic virus (MDM) and maize chlorotic dwarf virus (MCD). Both overwinter in johnsongrass and are usually present as a virus complex. Two locations (Frankfort and Henderson) were planted with 56 hybrids to evaluate resistance to the virus complex. Although johnsongrass was present at the Henderson location, virus symptoms were not apparent on the corn hybrids and no virus ratings were taken. The high yield levels of the hybrids at the Henderson location reflect the absence of disease. More johnsongrass was present at the Frankfort location than at Henderson but was confined by cultivation to borders and alleys of the test area. Virus ratings taken at the Frankfort location reflect both the number of plants infected and the severity of infection to those plants. The ratings shown in Table 15 are the weighted averages of virus infected and noninfected plants evaluated August 6. A rating of 1 indicates that the hybrid was completely healthy and no plants were infected whereas a rating of 9 indicates that all plants of this hybrid were killed by the virus disease. A rating of 3 or lower indicates

that the hybrid has some resistance in that few plants were infected or that those infected did not have a visual appearance of severe virus damage.

### **Maturity Comparisons**

Three open-pedigree hybrids (FR27 x LH38, FR27 x Mo17, and FR27 x Pa91) were included in each non-virus test to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc. The relative maturities of these hybrids for Kentucky as rated by Illinois Foundation Seed, Inc. are Early-, Mid-, and Late-Season, respectively. The relative maturity ratings were quite appropriate since the harvest moistures of the hybrids when averaged across all non-virus locations, Table 11, were 18.0% for FR27 x LH38, 19.3% for FR27 x Mo17, and 21.9% for FR27 x Pa91. Harvest maturity of other hybrids in the test can be judged by comparison of harvest moisture relative to these checks and other hybrids of known maturity for your area of production.

## **ABOUT THE GROWING SEASON**

### **BARDWELL (Carlisle County)**

The Bardwell test was planted no-till on April 29 in corn and wheat residue. A last minute site change resulted in a no-till rather than a conventional-till test. The test appeared to be doing well on June 17 with the only pest problem being johnsongrass. Mid and/or late season drought very likely reduced hybrid yields. Although virus ratings were not taken, observations at harvest suggested that the plants were probably infected with corn virus diseases which would have contributed to the low yields at this location.

### **PRINCETON (KAES, Research and Education Center)**

The Princeton test was planted on April 23. Weed control was poor. Evik was hand sprayed during June to control broadleaf weeds and grasses in the alleyways. Drought reduced yields.

### **RUSSELLVILLE (Logan County)**

The Russellville test was planted on April 8. A late season frost during April damaged some leaves.

Weed control was good although a minor infestation of johnsongrass occurred in the alleyways. There were no apparent disease or insect problems.

### **MORGANFIELD (Union County)**

The Morganfield test was planted on April 9. Inadequate rainfall in the early season caused herbicide failure and subsequent weed problems. Some plots in low areas suffered water damage from heavy May rainfall. Evik herbicide was hand sprayed to control weed infestations in the alleyways. Disease and insect problems were minimal.

### **SHELBYVILLE (Shelby County)**

The Shelbyville test was planted no-till on April 30 in wheat/soybean stubble. Weed control was good. There were no apparent disease or insect problems.

### **LEXINGTON (KAES, Spindletop Research Farm)**

The Lexington test was planted on May 2. Weed control was poor and was probably caused by minimal rainfall immediately after planting that did not activate the weed control chemicals. The test was cultivated twice and a lay-by application of Aatrex and oil was applied. European Corn Borer caused some lodging problems. The test was harvested at a higher moisture content because of the excessive lodging. Mid to late season drought caused significant yield reductions.

### **QUICKSAND (KAES, Robinson Substation)**

The Quicksand test was planted on April 23. Weed control was fair. Broadleaf weeds and vines were oversprayed with Banvel. Alleyways were sprayed with Basagran to control nutsedge. Ratings of Gray Leaf Spot and other leaf diseases were taken by Drs. Stuckey and Hartman of the Plant Pathology Department. The results of these ratings may be obtained by contacting either Dr. Stuckey or Dr. Hartman, Department of Plant Pathology, University of KY, Lexington, KY 40546-0091. Other disease and insect problems were minimal.

### **HENDERSON (Henderson County)**

The Henderson test was planted on May 5. Weed control was good. Although virus symptoms were present on johnsongrass plants along the field border, no virus symptoms were visible on the corn plants when observed on June 18. There were no other apparent disease or insect problems.

### **FRANKFORT (Franklin County)**

The Frankfort test was planted on May 22. The soil was heavy at planting which probably contributed to leaching of weed control chemicals. Johnsongrass, both seedling and rhizome, heavily infested the test area. The test was cultivated twice and Roundup was used to control johnsongrass in the alleyways. Low stands at harvest were caused primarily by the virus diseases and to a lesser extent by cultivation and other weed control efforts.
