ACKNOWLEDGEMENTS

The authors are grateful to the Agricultural Data Center for assistance in summarizing the results presented in this progress report. Also, acknowledgements are made to the following people who helped conduct this year's performance test:

Dr. Morris Bitzer, Extension Specialist in Grain Crops, Lexington

Dr. John R. Hartman and Dr. Richard E. Stuckey, Department of Plant Pathology,
Lexington

Dr. James Herbek, Extension Specialist in Grain Crops, Research and Extension Center,
Princeton

Donnie Davis, Superintendent, Research and Education Center, Princeton

Mason Morrison, Superintendent, Robinson Substation, Quicksand

Darrel Tichenor, Extension Agent, Benton

Michael Smith, Extension Agent, Henderson

Don Kessler, Extension Agent, Franklin

Roger Sparrow, Extension Agent, Frankfort

Greg Henson, Extension Agent, Calhoun

Jack Snyder, Extension Agent, Elizabethtown

1989 Kentucky Hybrid Corn Performance Test

C.G. Poneleit and K.O. Evans

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

PRESENTATION OF DATA

Complete 1989 data are presented for the tests at each location harvested. Two- and three-year averages for yield are included in each of the single location tables. Readers are encouraged to consider these multiple year averages and the averages over locations (Tables 10, 11, and 12) since these are better estimates of a hybrid's yield ability than data gathered at one location in one year.

Comparisons between yields or other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location with another grown at a different location.

TESTING PROCEDURE

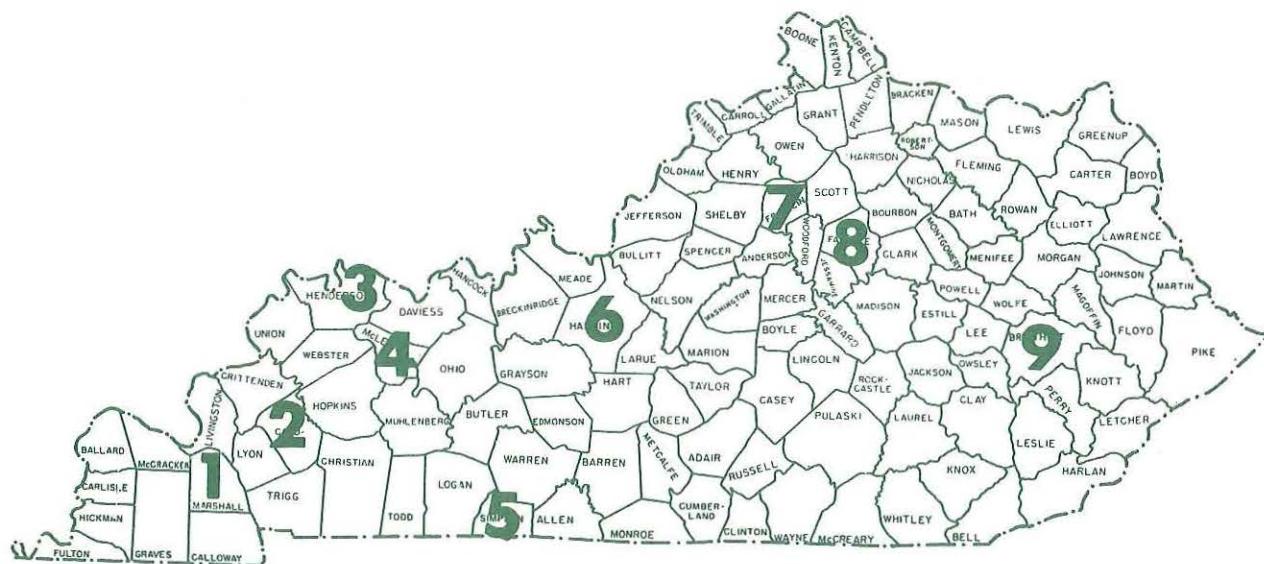

Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 1990. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company. An incorrect seedlot of Pioneer Brand 3165 was received and used in the 1989 test. Consequently, these data were not included.

Those hybrids grown in the corn virus tests are indicated in column 2 of Table 2. The hybrid corn companies were asked to nominate those hybrids known to have virus resistance for inclusion in the virus test.

Location of Tests

The map below shows the location for each test. The non-virus test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity. The Henderson and

* Locations of the 1989 Hybrid Corn Performance Test

Frankfort sites were chosen specifically for the presence of corn virus in diverse areas of the state and may represent differences in virus populations.

Cultural Practices

The seedbeds at each location except Elizabethtown and Benton were prepared by conventional tillage methods. Fertilizer was applied as indicated by soil tests. The test at Elizabethtown was planted in a soybean and triticale crop residue and at Benton in a wheat and soybean residue using recommended no-tillage practices. All test areas were treated with herbicide and supplemented by post-emergence cultivation and/or herbicide when necessary. Except for the virus tests, Counter was applied in the row at planting. Table 3 shows the specific cultural treatment for each location. The virus tests received Dyfonate as a surface applied insecticide at planting to control corn rootworms.

Experimental Design

Each hybrid was grown in three separate plots at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site while two- and three-year means are averages of six and nine replications, respectively. An 11 x 12 lattice design was used at each non-virus location, and an 8 x 8 lattice design was used at the virus locations.

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) quoted at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yielding ability. "N.S." in the tables indicates that no statistically significant differences were determined. The LSD is calculated for an α level of 0.10.

Planting

All plots were planted with a two-row, no-till planter modified for small plot work. The planter

boxes were replaced by special planting cones which allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 36 inches apart and 22 feet long. Each conventional tillage test was planted at the rate of 23,760 kernels per acre. The no-till test at Elizabethtown was planted at a rate of 25,740 kernels per acre. Final stands were expected to be between 20,000 and 22,000 plants per acre if average stand losses occurred.

Harvesting

All plots were harvested with a modified two-row self-propelled corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot were measured with an electronic scale and moisture meter mounted on the combine. Data from most test locations was temporarily stored in a portable data logging device prior to transfer to a computer at Lexington. Yields were calculated and adjusted to No. 2 corn at 15.5% moisture. Dropped ears were not gleaned from the plots. The total number of plants and lodged plants were recorded immediately prior to harvest.

Corn Virus

Two corn virus diseases occur in Kentucky: maize dwarf mosaic virus (MDM) and maize chlorotic dwarf virus (MCD). Both overwinter in johnsongrass and are usually present as a virus complex. Two locations (Frankfort and Henderson) were planted with 64 hybrids to evaluate resistance to the virus complex. Although johnsongrass was present at both virus locations and virus symptoms appeared in the johnsongrass, virus symptoms were not apparent on the corn hybrids and no virus ratings were taken.

Maturity Comparisons

Three open-pedigree hybrids (FR27 X LH38, FR27 X Mo17, and FR27 X Pa91) were included in each non-virus test to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc. The relative maturities of these hybrids for Kentucky as rated by Illinois Foundation Seeds, Inc. are Early-, Mid-, and Late-Season, respectively. The relative maturity ratings were quite appropriate since the harvest moistures of the hybrids when averaged across all non-virus locations (see Table 10) were 18.0% for FR27 X LH38, 19.4% for FR27 X Mo17, and 21.2% for FR27 X Pa91. Harvest maturity of other hybrids in the test can be judged by comparison of harvest moisture relative to these checks and other hybrids of known maturity for your area of production.

ABOUT THE GROWING SEASON

BENTON (Marshall County)

The Benton test was planted on May 3. The test was checked for seedling emergence on May 11 and on June 19. Plant populations were good. The test received adequate to surplus rainfall. Weed control was good with only late season weeds appearing in the alleyways. Plants in some plots appeared yellow, probably as a result of the loss of nitrogen by leaching from excessive rainfall. There were no disease problems. Lodging of plants in the test was caused primarily by the Southwestern corn borer.

PRINCETON (KAES, Research and Education Center)

The Princeton test was planted on May 1. The seedbed was in excellent condition; however, seedling emergence was poor and average stand was estimated to be only 40.0 to 45.0%. Excessive precipitation prevented timely replanting of the test. Weed control was good with only a few plants of johnsongrass in the alleyways. There were no apparent disease problems; however, there was some damage from the European and Southwestern corn borers. This test was not harvested because of the low plant population.

FRANKLIN (Simpson County)

The Franklin test was planted on April 24. Seedlings were emerging on May 11. Populations of some plots were poor. These lowered populations appeared to be related to the placement of anhydrous ammonia fertilizer that was applied immediately prior to planting. Weed control was good, except for johnsongrass which was heavy in some plots and the alleyways. There appeared to be no disease problems. The European and Southwestern corn borers caused some lodging in the test.

CALHOUN (McLean County)

The Calhoun test was planted on May 15. Weed control was good. When the test was checked on June 19 the corn plants were approximately 18 inches high. Alleyways were sprayed with Roundup on July 18 to control foxtail and fall panicum. The test appeared to have no disease or insect problems.

ELIZABETHTOWN (Hardin County)

The Elizabethtown test was planted on April 25. The test was planted no-till in triticale and soybean crop residue. The test was checked on May 12 and plant populations appeared to be good. Weed control was good for most weeds and grasses but there were a few isolated areas of johnsongrass and vines. The alleyways were sprayed on July 13 with Roundup for johnsongrass control. There appeared to be no disease problems. There was some clipping of silks by Japanese beetles.

LEXINGTON (KAES, Spindletop Research Farm)

The Lexington test was planted on April 26. Seedling emergence was good and weed control was excellent. There appeared to be no disease problems. There was some clipping of silks by Japanese beetles and June beetles but the clipping did not appear to cause any pollination problems.

QUICKSAND (KAES, Robinson Substation)

The Quicksand test was planted on May 18. Weed control was excellent. Late season cockleburs present in alleyways were removed manually. Disease and insect problems were minimal although late season gray leaf spot infection was present and may have affected the performance of susceptible hybrids.

HENDERSON (Henderson County)

The Henderson test was planted on May 30. Weed control, except for johnsongrass, was good. The test was cultivated on July 6 with a two-row tractor powered rotary tiller. The alleyways were sprayed on July 18 with Roundup for johnsongrass control. Johnsongrass around the plot area had virus symptoms but no symptoms were found on corn plants in the test. Virus disease ratings were not taken. There were no other disease or insect problems.

FRANKFORT (Franklin County)

The Frankfort test was planted on May 25. Weed problems were minimal. A hard rain shortly after planting caused poor seedling emergence. Con-

tinued excessive precipitation prevented timely replanting. The test was cultivated once to control both seedling and rhizome johnsongrass. Johnson-grass in the alleyways and around the plot area had virus symptoms but there were no apparent symptoms on the corn plants. Virus disease ratings were not taken. The Frankfort test was not harvested because of very low plant populations.

NOTE

All Western Kentucky locations were observed for potential problems on May 11 and 12 and again on June 18 and 19. Eastern Kentucky locations were checked on several occasions during the growing season.
