## ACKNOWLEDGEMENTS

The authors are grateful to the Agricultural Data Center and to Mr. Danny Walls for assistance in summarizing the results presented in this progress report. Also, acknowledgements are made to the following people who helped conduct this year's performance test:

- Dr. Morris Bitzer, Extension Specialist in Grain Crops, Lexington  
Dr. John R. Hartman and Dr. Paul C. Vincelli, Department of Plant Pathology, Lexington  
Dr. James Herbek, Extension Specialist in Grain Crops, Research and Extension Center, Princeton  
Donnie Davis, Superintendent, Research and Education Center, Princeton  
Mason Morrison, Superintendent, Robinson Substation, Quicksand  
Darrel Tichenor, Extension Agent, Benton  
Gene Brown, Extension Agent, Morganfield  
Don Kessler, Extension Agent, Franklin  
Roger Sparrow, Extension Agent, Frankfort  
Tom Curtsinger, Extension Agent, Owensboro  
Roy Catlet, Extension Agent, Shelbyville

# 1990 Kentucky Hybrid Corn Performance Test

C.G. Poneleit and K.O. Evans

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

## PRESENTATION OF DATA

Complete 1990 data are presented for the tests at each location harvested. Two- and three-year averages for yield are included in each of the single location tables. Readers are encouraged to consider these multiple year averages and the averages over locations (Tables 11, 12, and 13) since these are better estimates of a hybrid's yield ability than data gathered at one location in one year.

Comparisons between yields or other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location with another grown at a different location.

## TESTING PROCEDURE

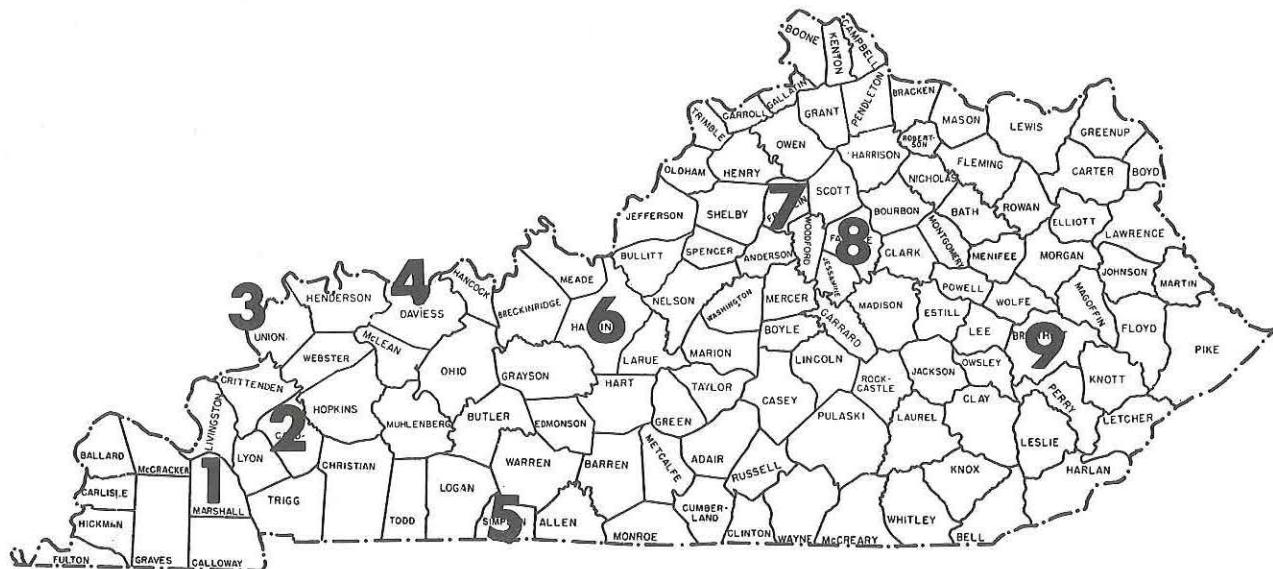

### Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 1991. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company.

Those hybrids grown in the corn virus tests are indicated with a B in column 2 of Table 2. The hybrid corn companies were asked to nominate those hybrids known to have virus resistance for inclusion in the virus test.

### Location of Tests

The map below shows the location for each test. The non-virus test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity. The Morganfield and Frankfort sites were chosen specifically for the presence of corn virus in diverse areas of the state and may represent differences in virus populations.

## Cultural Practices

The test locations at Shelbyville, Benton, and Princeton were planted no-till. The other locations were planted in a seedbed prepared by conventional tillage methods. Fertilizer was applied as indicated by soil tests. The tests at Shelbyville and Benton were planted in a soybean residue and at Princeton in a wheat residue using recommended no-tillage practices. All test areas were treated with herbicide and supplemented by post-emergence cultivation and/or herbicide when necessary. Except for the virus tests, Counter was applied in the row at planting to control corn rootworms. The virus test at Frankfort received Dyfonate as a surface applied insecticide. Table 3 shows the specific cultural treatment for each location.

## Experimental Design

Each hybrid was grown in three separate plots at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site (except Princeton, where only two replications are used), while two- and three-year means are averages of six and nine replications, respectively. An 11 x 12 lattice design was used at each non-virus location, and a 7 x 8 lattice design was used at the virus locations.

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) quoted at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yielding ability. "N.S." in the tables indicates that no statistically significant differences were determined. The LSD is calculated for an  $\alpha$  level of 0.10.

## Planting

All plots were planted with a two-row, no-till planter modified for small plot work. The planter boxes were replaced by special planting cones which allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 36

inches apart and 22 feet long. Each conventional tillage test was planted at the rate of 23,760 kernels per acre. The no-till test at Shelbyville was planted at a rate of 25,740 kernels per acre. Final stands were expected to be between 20,000 and 22,000 plants per acre if average stand losses occurred.

## Harvesting

All plots were harvested with a modified two-row self-propelled corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot were measured with an electronic scale and moisture meter mounted on the combine. Data from most test locations was temporarily stored in a portable data logging device prior to transfer to a computer at Lexington. Yields were calculated and adjusted to No. 2 corn at 15.5% moisture. Dropped ears were not gleaned from the plots. The total number of plants and lodged plants were recorded immediately prior to harvest.

## Corn Virus

Two corn virus diseases occur in Kentucky: maize dwarf mosaic virus (MDM) and maize chlorotic dwarf virus (MCD). Both overwinter in johnsongrass and are usually present as a virus complex. Two locations (Frankfort and Morganfield) were planted with 50 hybrids to evaluate resistance to the virus complex. Although johnsongrass was present at both virus locations and virus symptoms appeared in the johnsongrass, virus symptoms were not apparent on the corn hybrids at Morganfield and no virus ratings were taken. The Frankfort test plants did show virus symptoms and ratings were taken on September 9. No data were collected at the Morganfield site due to damage that occurred to many plots. See the notes about the Morganfield growing season.

The virus rating in Table 14 is an average rating for all plants in the plot. The number of virus infected plants was determined and a severity rating from 2 to 9 was assigned. Virus-free plants were given a 1 rating. The most severely affected plants, dead plants, were given a rating of 9. The sum of healthy plants ( $X$  1) plus infected plants ( $X$  severity rating) divided by the total of all plants equals the average rating shown in Table 14. For example, if 20 plants in a plot are diseased with a severity rating of 5 and 40 plants are healthy, the average virus rating for that plot is 2.3;  $((20 \times 5) + (40 \times 1)) / 60 = 2.3$ .

## **Maturity Comparisons**

Three open-pedigree hybrids (FR27 X LH38, FR27 X Mo17, and FR27 X Pa91) were included in each non-virus test to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc. The relative maturities of these hybrids for Kentucky as rated by Illinois Foundation Seeds, Inc. are Early-, Mid-, and Late-Season, respectively. The relative maturity ratings were quite appropriate since the harvest moistures of the hybrids when averaged across all non-virus locations (see Table 10) were 19.5% for FR27 X LH38, 21.9% for FR27 X Mo17, and 24.7% for FR27 X Pa91. Harvest maturity of other hybrids in the test can be judged by comparison of harvest moisture relative to these checks and other hybrids of known maturity for your area of production.

## **ABOUT THE GROWING SEASON**

### **BENTON (Marshall County)**

The Benton test was planted on May 15. The test was checked for seedling emergence on June 2. Plant populations were good. The test suffered yield losses because of the lack of timely rainfall. Weed control was good with only late season weeds in the alleyways. There were no disease problems. Lodging of plants in the tests was caused primarily by the Southwestern corn borer.

### **PRINCETON (KAES, Research and Education Center)**

The Princeton test was planted on June 1. Excessive rainfall during May prevented timely preparation of a conventional seedbed. The test was planted no-till in wheat residue and winter annuals. Uneven fertilizer application by a bulk spreader caused the plots to have an uneven appearance until late in the growing season and may have reduced some plot yields. Weed control was good, except for johnsongrass that originated from seed. Alleyways were sprayed twice to control the johnsongrass. There were no apparent disease problems; however, there was some damage from European and Southwestern corn borers.

### **FRANKLIN (Simpson County)**

The Franklin test was planted on April 25. Seedling emergence was good and mature stands were adequate. Weed control was excellent during the growing season. This test suffered severe yield losses, due to lack of adequate rainfall. There appeared to be no disease problems. The European and Southwestern corn borers caused some lodging.

### **OWENSBORO (Daviess County)**

The Owensboro test was planted on June 13. Weed control was fair. Mid-season weed control was accomplished with Gramoxone Extra, using a shielded sprayer, to control missed weeds and grasses. Alleyways were sprayed with Roundup on August 7 to control horseweed and fall panicum but control was not complete and there were some plants remaining at harvest. The test appeared to have no disease or insect problems.

### **SHELBYVILLE (Shelby County)**

The Shelbyville test was planted no-till in a soybean crop residue on April 23. The test was checked on May 12 and plant populations appeared to be good. Weed control was good for most weeds and grasses but there were a few isolated areas of shattercane and vines. There were no apparent disease problems.

### **LEXINGTON (KAES, Spindletop Research Farm)**

The Lexington test was planted on May 11. Seedling emergence was good and weed control was excellent. There appeared to be no disease problems. There was some clipping of silks by Japanese beetles and June beetles that infested the area during June and July but the silk clipping did not appear to cause pollination problems.

## **QUICKSAND (KAES, Robinson Substation)**

The Quicksand test was planted on May 24. Weed control was fair. The test was cultivated with a tractor mounted power tiller to control missed weeds and grasses on July 6. Late season cockleburs were removed manually. Disease and insect problems were minimal although late season gray leaf spot infection was present and may have affected the performance of susceptible hybrids.

## **MORGANFIELD (Union County)**

The Morganfield test was planted on June 19. Weed control, except for johnsongrass, was good. The test was cultivated on July 17 with a two-row tractor-powered rotary tiller. Some test plots were damaged by injector knives during nitrogen fertilizer application and while spraying for late season insect control. Johnsongrass around the plot area had virus symptoms but no symptoms were found on corn plants; thus, virus disease ratings were not taken. There was damage from European corn borer and army worms. This plot was **not** harvested due to the mechanical and insect damage plus the lateness of the test.

## **FRANKFORT (Franklin County)**

The Frankfort test was planted on June 18. Weed problems, except for johnsongrass, were minimal. Seedling emergence was good. The test was cultivated three times to control seedling and rhizome johnsongrass. Johnsongrass in spreader rows and around the plot area and susceptible corn plants in spreader rows had virus symptoms. Virus disease ratings were taken September 9. Harvest was completed on November 14 after a killing frost. Grain dry-down, however, was not complete since moisture content of almost all grain samples exceeded the highest calibrated moisture level of the analysis equipment (33.5%). Since accurate moisture measurements could not be made, all plot yield samples were assumed to be 35%. Because of the late or incomplete maturation, yield data presented in Table 14 may not be accurate measures of the hybrids' true yield potential since the killing frost may have stopped grain fill prematurely for some hybrids. Virus rating, however, was not affected by the late growing season and should provide a good estimate of virus tolerance.

## **NOTE**

All Western Kentucky locations were observed for potential problems during the months of June, July, and August. Eastern Kentucky locations were checked on several occasions during the growing season.
