

# 1993 Kentucky Hybrid Corn Performance Test

C. G. Poneleit and K. O. Evans

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

## PRESENTATION OF DATA

Complete 1993 data is presented for the tests at each location harvested. Two- and three-year averages for yield are included in each of the single location tables. Readers are encouraged to consider multiple year averages and the averages over locations (Tables 4, 5, and 6) since these are better estimates of a hybrid's yield ability than data gathered at one location in one year.

Comparisons between yields or other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location with another grown at a different location.

The yellow endosperm hybrids are grouped into early-, mid-, and late-maturity groups based on harvest moisture. Also, those hybrids that yield equally as high as the highest yielding hybrid, based on statistical evaluation, are indicated by an asterisk. See the MATURITY COMPARISONS and the EXPERIMENTAL DESIGN AND MEANS COMPARISONS text sections for more detail.

## TESTING PROCEDURE

### Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 1994. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company.

Those hybrids grown in the corn virus tests are indicated with a B in Column 2 of Table 2. The hybrid corn companies were asked to nominate those hybrids known to have virus resistance for inclusion in the virus test.

### Location of Tests

The map to the right shows the location for each test. The non-virus test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity. The Frankfort site was chosen specifically for the presence of corn virus.

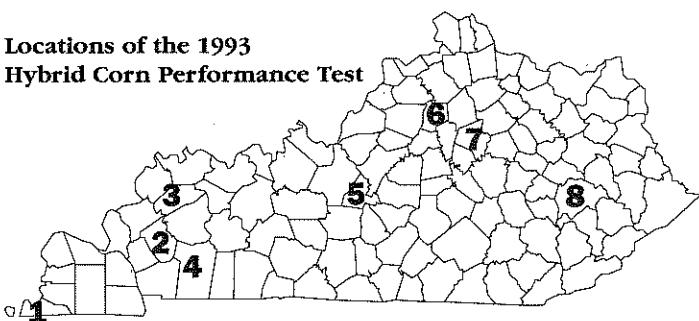

### LIST OF TABLES

- Table 1. Precipitation at 1993 Test Locations
- Table 2. Hybrids Tested in 1993
- Table 3. Agronomic Information for 1993 Test Locations
- Table 4. Annual Summary, 1993, All Non-Virus Locations
- Table 5. Two-Year Summary, All Non-Virus Locations, 1993-1992
- Table 6. Three-Year Summary, All Non-Virus Locations, 1993-1991
- Table 7. Annual Summary, Virus Test, Frankfort (map position 6)
- Table 8. Annual Summary, Hickman (map position 1)
- Table 9. Annual Summary, Princeton (map position 2)
- Table 10. Annual Summary, Dixon (Clay) (map position 3)
- Table 11. Annual Summary, Hopkinsville (map position 4)
- Table 12. Annual Summary, Hodgenville (map position 5)
- Table 13. Annual Summary, Lexington (map position 7)
- Table 14. Annual Summary, Quicksand (map position 8)

### Cultural Practices

The test locations at Hodgenville and Quicksand were planted no-till. The other test locations were planted in a seedbed prepared by conventional tillage methods. Fertilizer was applied as indicated by soil tests. The test at Hodgenville was planted in soybean residue using recommended no-tillage practices. The Quicksand test area was disked lightly prior to planting, but corn stalk and leaf residues were not covered by deep tillage so as to encourage Gray Leaf Spot (*Cercospora zeae-maydis*) spore production for later corn foliage infection. All test areas were treated with herbicide(s) and supplemented by post-emergence cultivation and/or herbicide when necessary. Except for the virus test, Furadan was applied in the row at planting to control corn rootworms. The virus test at Frankfort received no insecticide. Table 3 shows the specific cultural treatment for each location.

Locations of the 1993 Hybrid Corn Performance Test

## **Experimental Design and Mean Comparisons**

Each hybrid was grown in three separate plots at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site, while 2-year and 3-year means are averages of six and nine replications, respectively. An 11 x 12 lattice design was used at each non-virus location. A 7 x 7 lattice design was used at the virus location.

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) provided at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yield ability. "N.S." in the tables indicates that no statistically significant differences were determined. The LSD is calculated for an alpha level of 0.10. For your convenience, an asterisk has been placed alongside those yield means that are not significantly different from the highest yield mean in that column. This comparison means that those means followed by an asterisk do not differ by more than one LSD.

## **Planting**

All plots were planted with a two-row, no-till planter modified for small plot work. The planter boxes were replaced by special planting cones which allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 36 inches apart and 22 feet long. Each conventional tillage test was planted at the rate of 23,760 kernels per acre. The no-till test at Shelbyville was planted at a rate of 25,740 kernels per acre. Final stands were expected to be between 20,000 and 22,000 plants per acre if average stand losses occurred.

## **Harvesting**

All plots were harvested with a modified two-row self-propelled corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot were measured with an electronic scale and moisture meter mounted on the combine. Data from each test location were temporarily stored in a portable data logging device prior to transfer to a computer at Lexington. Yields were calculated and adjusted to 15.5% moisture. Dropped ears were not gleaned from the plots. The total number of plants and lodged plants were recorded immediately prior to harvest.

## **Corn Virus**

Two corn virus diseases occur in Kentucky: maize dwarf mosaic virus (MDM) and maize chlorotic dwarf virus (MCD). Both overwinter in johnsongrass and are usually present as a virus complex. The Frankfort test was planted with 47 nominated hybrids and two check hybrids to evaluate resistance to the virus complex. Virus symptoms did appear frequently on johnsongrass present in the plot area and on some corn plants. The virus ratings reflect both the number of plants infected and the severity of infection of those plants.

The virus ratings shown in Table 7 are called a virus rating index since it is an index of severity. It is calculated as the

weighted average of virus infected and noninfected plants. The plots were evaluated on September 22. A virus index value of 1 indicates that none of the hybrid plants in a plot displayed visible virus symptoms, while a virus index value of 9 indicates that all plants in the plot were dead. A virus index value greater than 3 indicates that the hybrid should be considered susceptible to the virus complex. A virus index value less than 3 indicates that either few plants were infected or those infected did not have severe, visible virus symptoms.

## **Maturity Comparisons**

Three open-pedigree hybrids (FR618 X FR600, FR27 X Mo17, and FR27 X Pa91) were included in each non-virus test to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc., at Champaign, IL, who rated the relative maturities of these hybrids for Kentucky, as Early-, Mid-, and Late-Season, respectively. The relative maturity ratings were appropriate since the harvest moistures of the hybrids, when averaged across all non-virus locations (Table 4), were 16.8% for FR618 X FR600, 17.7% for FR27 X Mo17, and 19.9% for FR27 X Pa91. Harvest maturity of other hybrids in the test can be judged by comparison of harvest moisture relative to these checks and other hybrids of known maturity for your area of production.

The yellow endosperm hybrids are separated into three maturity groups in each table. Groups were determined from the 1993 harvest moisture summary over all non-virus locations in Table 4. The early-season maturity hybrid group in Table 4, and all subsequent annual tables, are those hybrids that had a 1993 average harvest moisture of 17.3% or less. This group includes the early maturity hybrid FR618 X FR600 and all other hybrids with a 1993 average harvest moisture that was less than or equal to the harvest moisture of FR618 X FR600 plus one LSD ( $16.8\% + 0.5\% = 17.3\%$ ). Hybrids in this group were rated from 106 to 113 days maturity by the parent seed companies. Not all seed companies provided maturity day ratings.

The medium-season maturity group of yellow hybrids includes all hybrids with a 1993 average harvest moisture equal to or greater than 17.4% but equal to or lower than 19.3%. These limits are determined by the 1993 average harvest moisture of the early yellow hybrids upper limit (17.3%) and the late yellow hybrid lower limit (19.4%). Hybrids in this group were rated from 111 to 121 days maturity by the parent seed companies. Not all seed companies provided maturity day ratings.

The late-season maturity group of yellow hybrids are those that had an average 1993 harvest moisture equal to or greater than 19.4% which is one LSD less than the average harvest moisture of FR27 X Pa91 ( $19.9\% - 0.5\% = 19.4\%$ ). Hybrids in this group were rated from 114 to 125 days maturity by the parent seed companies. Not all seed companies provided maturity day ratings.

These groupings are subjective but provide an evaluation of hybrid maturity. Other post-harvest groupings may be equally as useful. The harvest moisture or relative maturity rating of a hybrid was not used to block hybrids in the field experiment.

The two- and three-year summaries in Tables 5 and 6 had early and late hybrid moisture ranges computed in similar manners.

## NOTES ABOUT THE GROWING SEASON

### Hickman (*Fulton County*)

The Hickman test was planted on May 21. The test was checked for seedling emergence on June 18. Plant populations were good. Weed control was only fair. There were heavy infestations of grasses in alleyways. Lodging associated with the test was caused by Southwestern corn borer. There were no apparent disease problems. The test suffered from lack of rainfall during the growing season.

### Princeton (*Ky. Agr. Exp. Sta., Research & Education Center*)

The Princeton test was planted on April 29. Seedling emergence was good on May 20. Weed control was poor. There were heavy infestations of cockleburs and johnsongrass, especially in the alleyways. Alleyways were mowed before harvest. There appeared to be no disease problems; however, European and Southwestern corn borers caused some lodging.

### Hopkinsville (*Christian County*)

The Hopkinsville test was planted on April 23. Seedling emergence and weed control were good when checked on May 20. The test hybrids were fully pollinated on July 9. Johnsongrass was removed by hand on July 20, and alleyways were sprayed with Roundup. There were no apparent disease or insect problems present at harvest. High wind and rain the latter part of August caused heavy root lodging in the test. The test lacked timely rainfall during the season.

### Dixon (*Clay*) (*Webster County*)

The Clay test was planted on May 27. Seedling emergence and weed control were good on June 18. Some late-season grasses and weeds were present in the alleyways at harvest. There was some European corn borer damage, which caused a few dropped ears. There were no apparent disease problems.

### Hodgenville (*Larue County*)

The Hodgenville test was planted no-till in soybean crop residue on April 28. The test was checked on June 4, and plant populations appeared to be good. There were a number of plots that had some rootless plants. Weed control was excellent. There were no apparent disease problems. Japanese beetles were present in the test during mid-July.

### Lexington (*Ky. Agr. Exp. Sta., Spindletop Research Farm*)

The Lexington test was planted on May 7. Seedling emergence was good, and weed control was good. Late-season grasses were present in alleyways at harvest. There were no disease problems. There was an infestation of Japanese beetles that clipped silks and may have reduced seed set for some hybrids. Sevin insecticide was applied on July 21 to reduce the beetle density. Although evaluation of beetle damage was not possible, it is likely that earlier hybrids may have suffered more silk clipping than later hybrids.

### Quicksand (*Ky. Agr. Exp. Sta., Robinson Substation*)

The Quicksand test was planted on May 6. Early-season weed control was good, and seedling emergence was good for most plots. The test was sprayed on June 2, with Beacon, to control johnsongrass and other missed weeds and grasses. Burcucumber vines and cockleburs were present in the test at harvest. Alleyways were mowed prior to harvest to remove cockleburs. There was no apparent insect problems. Gray Leaf Spot (GLS) ratings were taken on the test August 18 and September 9. These ratings are included in Table 14. The ratings are the average percent dead (necrotic) tissue on the ear leaf of 5 plants in each plot.

### Frankfort (*Franklin County*)

The Frankfort test was planted on June 12. Weed control was good, except for johnsongrass and burcucumber vines. Seedling emergence was good. The test was sprayed with Beacon on July 14 to control seedling and rhizome johnsongrass. The test was evaluated on September 21 for the virus complex. Japanese beetles clipped some silks during the pollinating season. There appeared to be no other insect or disease problems.

### Note

All Western Kentucky locations were observed for potential problems during the months of June, July, and August. Eastern Kentucky locations were checked on several occasions during the growing season.

### Acknowledgements

The authors are grateful to John Byars, Agricultural Data Center, and to Danny Walls, Agronomy Department, for assistance in summarizing the results presented in this progress report. Also, acknowledgements are made to the following people who helped conduct this year's performance test:

*Table 3. Agronomic Information Pertaining to 1993 Test Locations*

Location and Cooperator	Soil Type	Fertilizer Lb/AC	Herbicide	Insecticide	Planting Dates	Harvest Dates	Comments
1) Hickman, KY Major's Farm Route 1	Calloway Silt Loam	N - 192 P205 - 58 K20 - 90	Aatrex & Dual	Furadan	May 21	Oct. 7 & 8	
2) Princeton, KY Western Kentucky Res. & Ed. Center	Huntington & Lindsde Silt Loam	N - 150 P205 - 0 K20 180	Sutan +, Aatrex & Lasso	Furadan	April 29	Oct. 5 & 6	
3) Clay, KY Mitchell Brothers	Belnap Silt Loam	N - 240 P205 - 58 K20 - 75	Sutazine & Aatrex	Furadan	May 27	Oct. 14 & 15	
4) Hopkinsville, KY Smith Farm	Nicholson Silt Loam	N - 180 P205 - 80 K20 - 80	Bullet	Furadan	April 23	Sept 28 & 29	
5) Hodgenville, KY George Pickeral	Elk Silt Loam	N - 200 P205 - 114 K20 - 60	Bullet, 2,4-D, & Roundup	Furadan	April 28	Sept. 30 & Oct. 1	No-Till Soybean Residue
6) Frankfort, KY Tommy Quarles	Nolin Silt Loam	N - 152 P205 - 0 K20 - 50	Sutan +, Aatrex & Beacon	None	June 17	Nov. 11	
7) Lexington, KY K.A.E.S. Spindletop Farm	Lanton Silt Loam	N - 150 P205 - 0 K20 - 100	Sutan +, Aatrex & Lasso	Furadan & Sevin	May 7	Sept. 21 & 22	
8) Quicksand, KY Robinson Forest Station	Philo Silt Loam	N - 160 P205 100 K20 - 100	Lasso, Aatrex & Beacon	Furadan	May 6	Oct. 25 & 26	No-Till Corn Residue

\* In any yield column, a hybrid mean followed by an asterisk does not differ significantly (less than or equal to one LSD) from the highest yielding hybrid mean in that column.

\*\* Average contains data from two unreported experimental hybrids.
