

1995 Kentucky Hybrid Corn Performance Test

C.G. Poneleit, K.O. Evans and William L. Pearce

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

Presentation of Data

Complete 1995 data is presented for the tests at each location. Two-and three-year averages for yield are included in each of the single location tables. Readers are encouraged to consider these multiple year averages and the averages over locations (Tables 4, 5, and 6) since these are better estimates of a hybrid's yield ability than data gathered at one location in one year.

Comparisons between yields or other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location with another grown at a different location. Yellow endosperm hybrids are grouped into early-, mid-, and late-maturity groups based on harvest moisture. Also, those hybrids that yield equally as high as the highest yielding hybrid, based on statistical evaluation, are indicated by an asterisk. See the MATURITY COMPARISONS and the EXPERIMENTAL DESIGN AND MEANS COMPARISONS text sections for more detail.

Testing Procedure

Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 1996. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company.

Those hybrids grown in the corn virus test are indicated with a B in column 2 of Table 2. The hybrid corn companies were asked to nominate those hybrids known to have virus resistance for inclusion in the virus test.

Location of Tests

The map on page 1 shows the test locations. The non-virus test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity. The virus evaluation site was located at Frankfort.

Cultural Practices

The test location at Hodgenville was planted no-till in soybean residue using recommended no-tillage practices. The tests at Elkton and Quicksand were planted minimum-till in

LIST OF TABLES

- Table 14.—Gray Leaf Spot Evaluation, Stanford (map position 8)

corn stalk residue. The other test locations were planted in a seedbed prepared by conventional tillage methods. Fertilizer was applied as indicated by soil tests.

All test areas were treated with herbicide(s) and supplemented by post-emergence cultivation and/or herbicide when necessary. Except for the virus test, Force was applied in the row at planting to control corn rootworms. The virus test received no insecticide. Table 3 shows the specific cultural treatment for each location.

Experimental Design and Mean Comparisons

Each hybrid was grown in three separate plots at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site, while 2-year and 3-year means are averages of six and nine replications, respectively. An 11 x 12 lattice design was used at each non-virus location. A 7 x 6 lattice design was used at the virus location.

Locations of the 1995 Hybrid Corn Performance Test

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) provided at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yield ability. Consider the following example:

Variety	Yield(bu/a)
A	130
B	125
C	120
LSD (0.10)	= 8.0

The deviation between variety A and variety B is 5 bu/a ($130-125=5$). The difference is smaller than the LSD (8 bu/a). We can thus infer with reasonable confidence that variety A and B have the same yield in this test. However the difference between variety A and C is 10 bu/a ($130-120=10$) which is larger than the LSD of (8 bu/a). Therefore we can infer that variety A yielded more than variety C in this test. "N.S." in the tables indicates that no statistically significant differences was determined. The LSD is calculated for an alpha level of 0.10. For your convenience, an asterisk has been placed alongside those yield means that are not significantly different from the highest yield mean in that column. This comparison means that those means followed by an asterisk do not differ by more than one LSD.

The coefficient of variation (C.V.) is a measure of the accuracy of the results of a given variety trial and is used to evaluate the precision of the trials. This is usually the amount of unexplained variation that exists between varieties within a trial. So the lower the C.V. the more precise the results.

Planting

All plots were planted with a two-row, no-till planter modified for small plot work. The planter boxes were replaced by special planting cones which allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 36 inches apart and 22 feet long. Each conventional tillage test was planted at the rate of 23,760 kernels per acre. The no-till test at Hodgenville was planted at a rate of 25,740 kernels per acre. Final stands were expected to be between 20,000 and 22,000 plants per acre if average stand losses occurred.

Harvesting

All plots were harvested with a modified two-row corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot was measured with an electronic scale and moisture meter mounted on the combine. Data from each test location was temporarily stored in a portable data logging device prior to transfer to a computer at Lexington. Yields were calculated and adjusted to 15.5% moisture. Dropped ears were not gleaned from the plots. The total number of plants and lodged plants were recorded immediately prior to harvest. One data replication at the Murray, Ky test and one replication at the

Elkton, Ky test were deleted because of excessive numbers of missing plants caused by a planter malfunction.

Corn Virus

Two corn virus diseases occur in Kentucky: maize dwarf mosaic virus (MDM) and maize chlorotic dwarf virus (MCD). Both overwinter in johnsongrass and are usually present as a virus complex. The virus test was planted with 36 nominated hybrids and six check hybrids. Virus symptoms were present on some isolated johnsongrass plants along the edge of the plot area. However, no symptoms were present in the test.

Unfortunately, the test was located very near a stream that overflowed and caused serious damage to numerous plots in the first replication. Also, plot areas in the second and third replications had "wet spots" that obviously affected plant growth. The yield results were significantly affected; the test had a C.V. of nearly 30%. In our judgment the high C.V. and lack of meaningful virus infection made the remaining data much less meaningful and perhaps misleading. Consequently, we have not reported the 1995 Virus Test results.

Gray Leaf Spot

Data on the severity of gray leaf spot were collected on two dates by Dr. P. Vincelli (Extension Plant Pathologist, Department of Plant Pathology, University of Kentucky) at a special planting of all hybrids at a Lincoln, Co. site near Stanford, KY. On each date, the percentage of blighting due to gray leaf spot was estimated visually on the ear leaf on five randomly selected plants in each plot. The 1995 data are presented in Table 14 and were analyzed and adjusted by the lattice procedure as used for all other test variables. These results may be compared to prior year evaluations at Hopkinsville, KY in 1994 and at Quicksand, KY in 1993 and earlier (contact Dr. Vincelli for 1993 and previous year's data).

Gray leaf spot developed late in the season and was likely not a major determinant of yield for most hybrids tested. However, these data provide some indication of relative susceptibility to gray leaf spot and may be useful in selecting hybrids for sites where gray leaf pressure is heavy, particularly fields under no-till continuous corn production. Several years of gray leaf spot ratings should be examined before selecting a hybrid with partial resistance to the disease, since hybrid reactions vary under different environmental conditions.

Maturity Comparisons

Three open-pedigree hybrids (FR618 X FR600, FR27 X Mo17, and FR27 X Pa91) were included in each non-virus test to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc., at Champaign, IL, who rated the relative maturities of these hybrids for Kentucky, as Early-, Mid-, and Late-Season, respectively. The seven location harvest moisture averages for 1995 were 15.4% for FR618 X FR600, 15.6% for FR27 X Mo17, and 16.8% for FR27 X Pa91 (Table 4). Harvest maturity of other hybrids in the test can be judged by comparison of harvest moisture relative to these checks and other hybrids of known maturity for your area of production.

The yellow endosperm hybrids were separated into three maturity groups using the 1995 harvest moisture summary over all non-virus locations in Table 4. The early maturity hybrid group in Table 4, and all subsequent tables, are those hybrids

that had a 1995 average harvest moisture equal to or less than 15.4%, the moisture of the early check FR18 x FR600. Hybrids in the early group were rated from 110 to 115 days maturity by the parent seed companies.

The lower limit of the late maturity hybrid group, 16.8%, was calculated as the moisture content of FR27 X Pa91. All hybrids that were equal to or greater than this value were placed in this late maturity group. Hybrids in this group were rated from 114 to 125 days maturity by the parent seed companies.

The medium maturity group of yellow hybrids includes all hybrids with a 1995 average harvest moisture equal to or greater than 15.4% (early check average) but lower than 16.8% (late check average). Hybrids in the medium maturity group were rated from 113 to 119 days maturity by the parent seed companies.

These groupings are subjective but provide a relative evaluation of hybrid maturity. Additional information about hybrid maturity may be available from the parent seed company. The harvest moisture or relative maturity rating of a hybrid provided by the parent company was not used to block hybrids in the field experiment.

Notes About The Growing Season

Murray (Calloway County)

The Murray test was planted on April 19. Plant populations and early weed control were good except for replication 1. The previous crop was no-till wheat/soybeans.

Princeton (Ky. Agr. Exp. Sta., Research and Education Center)

The Princeton test was planted on May 11 in soybean residue. Stand counts were made on June 21. Weed control was fair but there were scattered infestations of johnsongrass and cocklebur especially in the alleyways. There appeared to be no disease problems, and no apparent insect problems

Elkton (Todd County)

The Elkton test was planted on May 31. Stand counts made on June 21 indicated that good stands had been established. There was some Southwestern corn borer damage in the test. Various vines species were present at harvest

Clay (Webster County)

The Clay test was planted on June 1. Stand counts were made on June 20. Johnsongrass and cocklebur were eliminated by hand spraying during the summer. At harvest some burcucumber was present. There was some Southwestern and European corn borer damage. There were no apparent disease problems.

Hodgenville (Larue County)

The Hodgenville test was planted no-till in soybean crop residue on May 12. Heavy rainfall (9.5") during the first week after planting caused soil compaction and poor seedling emergence on the first range. Stand counts were taken June 23 and were good. Weed control was excellent for the entire season. There was no apparent disease problems.

Lexington (Ky. Agr. Exp. Sta., Spindletop Research Farm)

The Lexington test was planted on April 28. Seedling emergence and weed control were good. Late season grasses in alleyways were sprayed with Roundup. There were no disease problems. Some Japanese beetles were present along the borders of the test.

Quicksand (Ky. Agr. Exp. Sta., Robinson Substation)

The Quicksand test was planted on May 26. Early season weed control and seedling emergence were excellent for most plots. The alleyways were sprayed to control johnsongrass and other missed weeds and grasses.

Frankfort (Franklin County)

The Frankfort virus evaluation test was planted on June 9. Alleyways were sprayed with Roundup to control late season grasses. There were no insect or disease problems. There were some severe lodging problems. Wet areas and overflow from a nearby stream caused late season plot damage that significantly affected yield and test variability. Virus ratings were not taken and agronomic data are not reported.

Note

All Western Kentucky locations were observed for potential problems during the months of June, July, and August. Eastern Kentucky locations were checked on several occasions during the growing season.

Acknowledgements

The authors are grateful to Mr. John Byars, Agricultural Data Center, and to Mr. Danny Walls, Agronomy Department, for assistance in summarizing the results presented in this progress report. Also, acknowledgements are made to the following people who helped conduct this year's performance test.

Table 3. Agronomic Information Pertaining to 1995 Test Locations

Location and Cooperator	Soil Type	Fertilizer Lb/Ac	Herbicide	Insecticide	Planting Dates	Harvest Dates
1) Murray, KY Carroway Farm	Calloway Silt Loam	N -176 P ₂ O ₅ -69 K ₂ O -90	Bicep Atrazine	Force 1.5G	April 19	Sept. 21
2) Princeton, KY Western Kentucky Res. & Ed. Center	Huntington & Lindside Silt Loam	N -188 P ₂ O ₅ -0 K ₂ O -133	Sutan Bullet Beacon	Force 1.5G	May 11 & 17	Oct. 16 & 17
3) Clay, KY Robbin Rhea	Collins Silt Loam	N -204 P ₂ O ₅ -75 K ₂ O -98	Beacon Clarity Bicep Atrazine Gramoxone	Force 1.5G	June 1	Oct. 18
4) Elkton, KY Allen Franks Farm	Pembroke	N -167 P ₂ O ₅ -159 K ₂ O -0	Bicep Atrazine Ambush	Force 1.5G	May 31	Oct. 11 & 12
5) Hodgenville, KY George Pickeral	Elk Silt Loam	N -175 P ₂ O ₅ -0 K ₂ O -100	Atrazine 2,4-D, Harness & Atrazine	Force 1.5G	May 12	Oct. 24 & 25
7) Lexington, KY K.A.E.S. Spindletop Farm	Lanton Silt Loam	N -150 P ₂ O ₅ -0 K ₂ O -100	Sutan+ & Aatrex & Lasso	Force 1.5G	April 28	Oct. 9 & 10
8) Quicksand, KY Robinson Forest Station	Philo Silt Loam	N -158 P ₂ O ₅ -87 K ₂ O -87	Sutan+ & Aatrex & Lasso & Beacon	Force 1.5G	May 26	Oct. 30 & 31
8) Frankfort, KY Allan Tracey	Huntington Silt Loam	N -153 P ₂ O ₅ -0 K ₂ O -120	Aatrex & Sutan+	None	June 6	Nov. 10
