

2012 Kentucky Hybrid Corn Performance Test

B. Bruening, R. Curd, J. Cole, W. Pearce, and C. Lee, Department of Plant and Soil Sciences

The objective of the Kentucky Hybrid Corn Performance Test is to provide performance estimates of hybrid seed corn sold in Kentucky. The test has been conducted in an unbiased manner according to accepted agronomic practices.

Presentation of Data

The 2012 hybrid performance data is presented for the tests across locations for single-year, two-year and three-year averages. Individual location data, when appropriate, is included as well. However, data across locations and years is a better predictor of hybrid performance. The multiple location data tables are the state summary tables.

Hybrids are grouped into four tests: Early, Medium, Late, and White. The Early test represents hybrids with relative maturities of 112 days or earlier, the Medium test represents hybrids with relative maturities of 113 to 117 days, and the Late test represents hybrids with relative maturities of 118 days or later. The White test represents hybrids with a white seed coat and a relative maturity of 112 to 118 days. Comparisons made between yields (and any other characteristics) of any two or more hybrids should be made with data from one table at a time. Hybrids should not be compared across tables. Hybrids that are likely to yield as high as the highest-yielding hybrid, based on statistical evaluation, are indicated by an asterisk. See the "Hybrid Comparisons" and "Experimental Design and Means Comparisons" text sections for more detail.

Testing Procedure

Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 2013. Seed of each commercial hybrid (Table 3) was obtained from the sponsoring company. Each company defined the maturity of their hybrids and was given the opportunity to identify the proper tests for their hybrids. Each company paid for the entry of their hybrid(s) into the test.

Location of Tests

The map on Page 1 shows the test locations. The test sites were selected to represent different agroclimatic areas of Kentucky where corn is a major commodity.

Cultural Practices

Corn seed was planted no-till into soybean stubble at all locations. Fertilizer was applied as indicated by soil tests.

All test areas were treated with herbicide(s) and insecticide(s). Force insecticide was applied in the row at planting to control corn rootworms. Seed corn may have been treated per each company's prerogative.

Experimental Design and Mean Comparisons

Each hybrid was grown in three replications at each location to sample uncontrollable variability within the field. Annual mean yields presented in the tables are averages of three

<http://www.ca.uky.edu/cornvarietytest/>

replications at the test site, while two-year and three-year means are averages of six and nine replications, respectively. A randomized complete block design (RCBD) was used for each test at each location.

These tests are designed to predict relative yield ability. In such a test, we are most interested in how Hybrid A yields relative to Hybrid B. Slight differences in yield ability can occur as a result of variability in the field. The least significant difference (LSD) is used to account for that variability and to help determine significant differences between hybrid performances. The LSD is calculated for each test.

Consider the following example:

Hybrid	Yield (bushel per acre)
A	165
B	155
C	140
LSD (0.10)	12

The yield difference between Hybrid A and Hybrid B is 10 bu/acre ($165 - 155 = 10$). The difference is less than the LSD (12 bu/acre). Based on the LSD, the yield difference between hybrids A and B is not significant, meaning we would expect hybrids A and B to have similar yields next season. However the yield difference between hybrids A and C is 25 bu/acre ($165 - 140 = 25$) which is greater than the LSD (12 bu/acre). The LSD indicates that we would expect Hybrid A to yield more than Hybrid C next year.

The LSD occurs at the bottom of each table. Yields that are less than the LSD are not significantly different from each other. An asterisk has been placed alongside yields that are not significantly different from the highest yield mean in that column. In addition, the tables are sorted from greatest yield to least yield.

The coefficient of variation (CV) is a calculated value that helps indicate unexplained variation in the studies. A smaller CV indicates less unexplained variation and more precise results. Typically, a CV of about 15 or less is expected in hybrid performance tests. A CV greater than 15 indicates too much unexplained variability, and the test is not suitable for hybrid selection decisions.

Planting

All plots were planted with a John Deere Maxi-Emerge vacuum, two-row, no-till planter modified for small-plot work. Two-row plots are suitable for comparing performance of hybrids to one another. Modified planting cones replaced the planter boxes and allowed placement of a specified number of kernels per plot. Each hybrid seed was planted into plots consisting of two rows 30 inches apart and 22 feet long. Hybrid seed was planted at 40 seeds per row for each plot. When seedlings were 12 to 18 inches tall, the stands were thinned to 36 plants per row, equaling 28,000 plants per acre. Final stands reported in the tables are compared to the 28,000 plants per acre. Hybrids with stands less than 100 percent had low emergence rates.

Harvesting

All plots were harvested with a Massey Ferguson MF 8-XP two-row corn combine. Both rows of each two-row plot were harvested. The grain weight, moisture content, and test weight of corn from each plot was measured with an electronic scale and moisture meter mounted on the combine. Yields were calculated for grain at 56 pounds per bushel and adjusted to 15.5 percent moisture. The test weight reported in each annual table for any hybrid is not corrected for harvest moisture and is reported at the moisture content for that hybrid listed in that table. Dropped ears were not gleaned from the plots. The total number of lodged plants was recorded at harvest.

Hybrid Comparisons

The Kentucky Hybrid Corn Performance Test is divided into four tests: Early, Medium, and Late maturities and White hybrids. These divisions provide evaluations of the hybrid groups without competition biases. The divisions do not allow for comparisons across groups. For example, a hybrid in the Early test cannot be compared to a hybrid in the Late. The Early, Medium, Late, and White tests were grown at all six locations for a total of 18 tests.

- The Early maturity hybrid group in Table 4E and all subsequent "E" tables are hybrids rated by the parent seed company to mature in 112 days or earlier.
- The Medium maturity hybrid group in Table 4M and all subsequent "M" tables include those hybrids rated by the parent seed company to mature in 113-117 days.
- The Late maturity hybrid group in Table 4L and all subsequent "L" tables include those hybrids rated by the parent seed company to mature in 118 days or later.
- The White hybrid group in Table 4W and all subsequent "W" Tables include those hybrids with a white seed coat and rated by the parent seed company to mature in 112 to 118 days.

Open-pedigree hybrids of known maturity were included in each Early, Medium, and Late test to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc., at Champaign, Ill.

Grain moisture of hybrids in the Early, Medium, and Late tests should be within the LSD of the check hybrid grain moisture for that test. Hybrids with grain moisture above the LSD of the check hybrid likely belong in a later-maturing test. Each hybrid is placed in the Early, Medium, and Late tests based on the hybrid maturity defined by the company.

Comments About the 2012 Growing Season

The 2012 growing season was one of the driest and hottest on record. Rainfall was severely limiting at several locations. Drought conditions were so severe at Princeton that corn at that site was not harvested for the trials. The drought stress lead to some highly variable fields at other locations as well. For example, Graves County had CVs above 50 in some areas. Generally, we expect to have a CV at or below 15 to indicate a uniform test.

Severe drought can greatly skew the performance of hybrids. In some cases, differences in performance may be due to timing drought stress relative to timing of pollination or seed fill. For example, the Early test at Graves County had an average yield of 85 bushels per acre and a CV of 24.7. The Late test at Graves County had an average yield of 44.7 bushels per acre and a CV of 54. In general, the Late hybrids did much worse than the Early hybrids. In this case, the hybrids' performance is not based on drought tolerance or yield ability, but simply on the timing of when the corn tried to pollinate relative to the weather conditions.

At Princeton, maximum daily temperatures were above 99 degrees Fahrenheit for nine out of 10 days from June 28 through July 8, 2012. No rain fell the week prior to those high temperatures and only 0.02 inches fell during those high temperatures.

Acknowledgements

The authors sincerely appreciate efforts of the Kentucky Corn Promotion Council in providing a Massey Ferguson 8-XP Corn plot combine through a very reasonable lease agreement.

The authors are grateful to the following farmer-cooperators who not only provided land for testing but helped with the tests throughout the growing season:

The Griffith Family of Graves County, Ky.

John Camp and family of Todd County, Ky.

Carlos Tucker and family of LaRue County, Ky.

Tony McCarty and family of Daviess County, Ky.

Joe Williams and Scott Peek, University of Kentucky Research and Education Center, Princeton, Ky.

The authors give special thanks to Ted Walker, John Stanhope, and the entire crew of the College of Ag Farm Shop for keeping us going year round.

Additional acknowledgements are made to the following people who helped conduct this year's performance test:

Richard C. Green, research technician, Plant and Soil Science Department, Lexington, Ky.

Dr. James Herbek, extension specialist in grain crops, University of Kentucky Research and Extension Center, Princeton, Ky.

Dennis Duross and Pati Ray, communication specialists, Agricultural Communications, Lexington, Ky.

Kenny Perry, extension agent, Graves County, Ky.

Curtis Judy, extension agent, Todd County, Ky.

Clint Hardy, extension agent, Daviess County, Ky.

David Harrison, extension agent, LaRue County, Ky.

Table 1. Average Yield and Coefficient of Variance Values.

Region	County	Test	Average Yield (BU/A)	CV*
