

# 2002 Kentucky Hybrid Corn Performance Test

William L. Pearce, Ron W. Curd, and Dr. Chad Lee

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

## Presentation of Data

Complete 2002 data are presented for the tests at each location. Two- and three-year averages for yield are included in each of the single location tables. Readers are encouraged to consider these multiple-year averages and the averages over locations (Tables 4E-1YR, 4E-2YR, 4E-3YR, 5M-1YR, 5M-2YR, 5M-3YR, 6L-1YR, 6L-2YR, 6L-3YR, 7W-1YR, 7W-2YR and 7W-3YR) since these are better estimates of a hybrid's yield ability than data gathered at one location in one year.

Comparisons between yields and other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location in one maturity group test with another grown at a different location and of the same or different maturity group test. Hybrids are grouped into early, medium, late, and white maturity groups based on days-to-maturity classifications provided by the parent company. Also, those hybrids that yield equally as high as the highest yielding hybrid, based on statistical evaluation, are indicated by an asterisk. See the sections on *Maturity Comparisons* and *Experimental Design and Mean Comparisons* for more detail.

## Testing Procedure

### Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 2003. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company. Each company was given the opportunity to enter hybrids into the early (112 days to maturity or earlier), medium (113 to 117 days to maturity), late (118 days to maturity or later), and/or white (112 to 118 days to maturity) tests. The days-to-maturity classifications were made by the parent companies.

### Location of Tests

The map on page 1 shows the test locations. The test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity.

### Cultural Practices

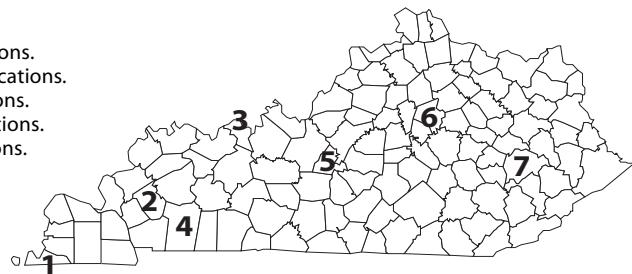

Test locations in Princeton, Hopkinsville, Fulton, Lewisport, Hodgenville, and Lexington were planted no-till in soybean residues. The Quicksand test was planted in conventionally tilled seedbeds following a cover crop of rye. Fertilizer was applied as indicated by soil tests.

All test areas were treated with herbicide(s) and supplemented by post-emergence cultivation and/or herbicide when necessary. Force was applied in the row at planting to control corn rootworms. Table 3 shows the specific cultural treatment for each location.

### List of Tables

- Table 1. Precipitation at Test Locations 2002.
- Table 2. Hybrids Tested in 2002.
- Table 3. Agronomic Information for 2002 Test Locations.
- Table 4. Early Hybrids, Annual, Two-Year, and Three-Year Summaries, All Locations.
- Table 5. Medium Hybrids, Annual, Two-Year, and Three-Year Summaries, All Locations.
- Table 6. Late Hybrids, Annual, Two-Year, and Three-Year Summaries, All Locations.
- Table 7. White Hybrids, Annual, Two-Year, and Three-Year Summaries, All Locations.
- Table 8. Annual Summary, Chemical Composition, E,M,L,W Hybrids, All Locations.
- Table 9. Annual Summary, Fulton, E,L,M,W Hybrids (map position 1).
- Table 10. Annual Summary, Princeton, E,L,M,W Hybrids (map position 2).
- Table 11. Annual Summary, Lewisport, E,L,M,W Hybrids (map position 3).

### Locations of the 2002 Hybrid Corn Performance Test

E=Early, M-Medium, L=Late, W=White

## *Experimental Design and Mean Comparisons*

Each hybrid was grown in three replications at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site, while two-year and three-year means are averages of six and nine replications, respectively. A randomized complete block (RCB) design was used for each maturity group test at each location.

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) provided at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yield ability. Consider the following example:

Variety	Yield (bu/ac)
A	135
B	125
C	110

$$\text{LSD (0.10)} = 12.0$$

The deviation between variety A and variety B is 10 bu/ac ( $135 - 125 = 10$ ). The difference is smaller than the LSD (12 bu/ac). We can thus infer with reasonable confidence that variety A and variety B have the same yield in this test. However, the difference between variety A and variety C is 25 bu/ac ( $135 - 110 = 25$ ), which is larger than the LSD (12 bu/ac). Therefore, we can infer that variety A yielded more than variety C in this test. "N.S." in the tables indicates that no statistically significant differences were determined. The LSD is calculated for an alpha level of 0.10. For your convenience, an asterisk has been placed alongside those yield means that are not significantly different from the highest yield mean in that column. This comparison indicates that those means followed by an asterisk do not differ by more than one LSD.

The C.V. expresses the amount of variation as a percentage of the hybrid mean. A low C.V. indicates little unexplained variation and more precise results.

## *Planting*

All plots were planted with a two-row, no-till planter modified for small plot work. The planter boxes were replaced by modified planting cones that allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 30 inches apart and 22 feet long. Each plot was planted with 40 seeds per row. When seedlings were 12 to 18 inches tall, the plots were thinned to 33 plants per row, which equals a plant population of 26,000 plants per acre.

## *Harvesting*

All plots were harvested with a MF 8-XP two-row corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot was measured with an electronic scale and moisture meter mounted on

the combine. Data from each test location were temporarily stored in a portable data-logging device prior to transfer to a computer at Lexington. Yields were calculated for grain at 56 pounds per bushel and adjusted to 15.5% moisture. Test weight was also provided by the electronic weighing device. The test weight reported in each annual table for any hybrid is not corrected for harvest moisture and is reported at the moisture content for that hybrid listed in that table. Dropped ears were not gleaned from the plots.

The total number of lodged plants was recorded immediately prior to harvest. Also at harvest, selected plots were observed to indicate apparent European corn borer damage by counting the number of broken tops per plot (personal communication, Dr. Ric Bessin, Department of Entomology, University of Kentucky). The most severe indications of Southwestern and some European corn borer damage (> 50% broken tops) were observed at the Princeton, Lewisport, Fulton, and Lexington locations. The least damage was observed at the Hopkinsville, Hodgenville, and Quicksand locations (5% to 15% broken tops). In general, Bt hybrids had less apparent corn borer damage than non-Bt hybrids.

## *Chemical Analysis of the Early, Medium, and Late Tests*

Chemical composition was measured from one replication of each early, medium, late, and white maturity test at each location. These samples were analyzed by the Kentucky Grain Quality Laboratory at Lexington<sup>1</sup> using Near Infrared Reflectance Spectroscopy (NIRS). The NIRS analysis provided evaluation of protein, starch, and oil and is presented in Table 8 for grain at 0% moisture.

Since grain used in feed rations contains some moisture, the composition variables provided in Tables 8 and 16 should possibly be used at a moisture content that is different from the 0% shown in Tables 8 and 16. To convert to a suitable moisture content, for example, 15% moisture, multiply the values in Tables 8 or 16 by 0.85. For any other moisture content, multiply the values by  $(100 - \% \text{ moisture})/100$ .

## *High Oil Tests*

High oil hybrid blends (TC High Oil Blend®) were tested at three locations. The yield and composition information will be useful to farmers feeding high oil (high energy) grain to livestock and to those participating in the high oil, value-added grain market. The tests had nine entries at three locations with three replications per location. The Lexington location was dropped due to high variation (> 20%). The two-location average yield data are available in Table 16C.

A 20- to 25-plant hand-pollinated sample from each replication of the Lexington test was analyzed for chemical composition. The grain was analyzed using NIRS by Wei Chen in the Grain Quality Laboratory, located in the Biosystems and Agricultural Engineering Building at the University of Kentucky, under the direction of Dr. Michael Montross. The chemical composition values presented in Table 16F are given for grain at 0% moisture.

<sup>1</sup> The Grain Quality Laboratory is a service provided by the University of Kentucky Agronomy Department with funding from the Kentucky Corn Growers Association.

## **Maturity Comparisons**

The division of the Kentucky Hybrid Corn Performance Test into four tests—early, medium, late, and white maturities—was to provide evaluations of the four maturity group hybrids without competition biases. The four tests were grown at every location for a total of 28 tests.

The early maturity hybrid group in Table 4E, and all subsequent “E” tables, includes those hybrids rated by the parent seed company to mature in 112 days or earlier.

The medium maturity hybrid group in Table 4M, and all subsequent “M” tables, includes those hybrids rated by the parent seed company to mature in 113 to 117 days.

The late maturity hybrid group in Table 4L, and all subsequent “L” tables, includes those hybrids rated by the parent seed company to mature in 118 days or later.

The white maturity hybrid group in Table 4W, and all subsequent “W” tables, includes those hybrids rated by the parent seed company to mature in 112 to 118 days.

The open-pedigree hybrids were included in each early, medium, and late test, respectively, to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds Inc., at Champaign, Illinois.

## **Notes about the 2002 Growing Season**

### **Fulton (Fulton County)**

The Fulton County test was planted on April 10 and 11. The test was thinned on May 30. Plant populations were affected by cold soil temperatures, especially in the medium test where the second replication was dropped. The weed control was good throughout the growing season. The previous crop was soybeans. Southwestern corn borers (> 50%) caused some damage to the entire crop. There was also a high oil test at this location.

### **Princeton (Kentucky Agricultural Experiment Station, Research and Education Center, Caldwell County)**

The Princeton test was planted on April 18 in soybean residue and thinned on June 7. Weed control was good during the entire season. This location had considerable damage due to Southwestern corn borers (> 50%) but little injury due to European corn borer.

### **Hopkinsville (Christian County)**

The Hopkinsville test was planted on April 19 and thinned on June 6. Weed control was good, with giant ragweed coming on late in the growing season. This location had little or no damage due to Southwestern corn borer (< 10%).

### **Lewisport (Hancock County)**

The Hancock County test was planted late on May 22 in soybean residue and thinned on June 25. There were no weed problems during the growing season. A high oil test was also grown at this location. This location had both European and Southwestern corn borer damage (> 50%).

### **Hodgenville (LaRue County)**

The Hodgenville test was planted no-till in soybean crop residue on April 16 and thinned on May 31. Weed control was good during most of the growing season with some late-season weeds coming on. There were no disease problems but some damage due to Southwestern corn borer (20%).

### **Lexington (Kentucky Agricultural Experiment Station, Spindletop Research Farm, Fayette County)**

The Lexington test was planted on April 24. The early and national white corn tests were replanted on May 24 because of frost damage. The medium, late, and white tests were thinned on June 12. The early and national white tests were thinned on June 24. A high oil test was also grown at this location. This location had excellent weed control during the entire season. There was damage due to Southwestern and European corn borer (> 50%). The early and TC high oil tests were dropped due to variation higher than 20%.

### **Quicksand (Kentucky Agricultural Experiment Station, Robinson Substation, Breathitt County)**

The Quicksand test was planted on May 16 and thinned on June 26. Early-season weed control and seedling emergence were excellent for most plots. This location had minimal cultivation to break up the soil, which was packed due to heavy rainfall in May. This location had little or no lodging and excellent rainfall during the entire growing season. This location had minimal damage due to Southwestern corn borer (< 15%).

## **Note**

All Western Kentucky locations were observed for potential problems during the months of June, July, and August. Eastern Kentucky locations were checked on several occasions during the growing season. Several locations suffered reduced yields due to extreme drought conditions during the growing season.

## Acknowledgments

The authors sincerely appreciate the efforts of the Kentucky Corn Growers Association in helping us upgrade plot equipment. A MF 8-XP combine was leased to the corn project at minimal cost by the Kentucky Corn Promotion Council of the Kentucky Corn Growers Association. This combine contributed to improved accuracy of the data, which is reflected in lower C.V.s. This combine uses a data collection system that provides test weight data along with yield and moisture.

The authors are also grateful to Dr. Michael Montross, Wei Chen (research analyst), and the Kentucky Corn Growers Association for the Grain Quality Laboratory, which processed more than 900-grain samples, and to the following farmer-co-operators who not only provided land for testing but also helped with the tests throughout the growing season: Rob and Robert Garrigan and family of Fulton, Jim Shelton of Hopkinsville, David Ragland and family of Hodgenville, and Steve and Shelby Emmick and family of Lewisport.

The authors also acknowledge the statistical and programming support of Dr. Paul L. Cornelius and Danny Walls of University of Kentucky Agronomy Department.

Additional acknowledgments are made to the following people who helped conduct this year's performance test:

- Richard C. Green, Research Technician, Department of Agronomy, Lexington
- Dr. Morris J. Bitzer, Research Specialist in Grain Crops, Department of Agronomy, Lexington
- Dr. James Herbek, Extension Specialist in Grain Crops, Department of Agronomy, Research and Extension Center, Princeton
- Donnie Davis, Superintendent, and Royce Burchett, Farm Manager, Research and Education Center, Princeton
- David Ditsch, Superintendent, and William Bowling, Farm Manager, Robinson Substation, Quicksand
- Dennis Duross, Communications Specialist, Agricultural Communications Services, University of Kentucky, Lexington
- Cam Kenimer, Extension Agent, Fulton
- James Stone, Extension Agent, Hopkinsville
- Diane Perkins, Extension Agent, Hancock County
- David Harrison, Extension Agent, Elizabethtown
