

2003 Kentucky Hybrid Corn Performance Test

William L. Pearce, Ron W. Curd, and Dr. Chad Lee

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. Every effort has been made to conduct the test in an unbiased manner according to accepted agronomic practices.

Presentation of Data

Complete 2003 data are presented for the tests at each location. Two- and three-year averages for yield are included in each of the single location tables. Readers are encouraged to consider these multiple-year averages and the averages over locations (Tables 4E-1YR, 4E-2YR, 4E-3YR, 5M-1YR, 5M-2YR, 5M-3YR, 6L-1YR, 6L-2YR, 6L-3YR, 7W-1YR, 7W-2YR, and 7W-3YR) because these are better estimates of a hybrid's yield ability than data gathered at one location in one year.

Comparisons between yields and other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location in one maturity group test with another grown at a different location and of the same or different maturity group test. Hybrids are grouped into early, medium-, late-, and white-maturity groups based on days to maturity classification provided by the parent company. Also, those hybrids that yield equally as high as the highest yielding hybrid, based on statistical evaluation, are indicated by an asterisk. See the "Experimental Design and Mean Comparisons" and "Hybrid Comparisons" text sections for more detail.

Testing Procedure

Selection of Hybrids

The hybrids chosen for testing are those most likely to be available for sale in 2004. Seed of each commercial hybrid (Table 2) was obtained from the sponsoring company. Each company was given the opportunity to enter hybrids into the early (112 days to maturity or earlier), medium (113-117 days to maturity), late (118 days to maturity or later) and/or white (112-118 days to maturity) tests. The days-to-maturity classifications were made by the parent companies.

Location of Tests

The map below shows the test locations. The test sites were selected to represent different agroclimatic areas of the state where corn is a major commodity.

Cultural Practices

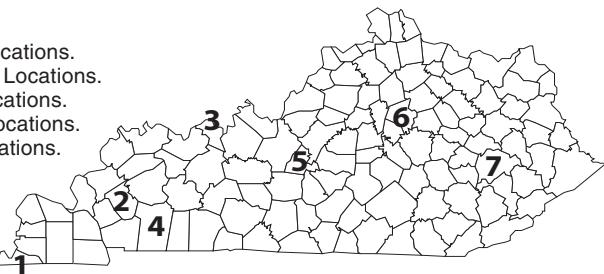

The Hopkinsville, Fulton, Lewisport, Hodgenville, and Lexington test locations were planted no-till in soybean residues. The Princeton test was planted no-till in wheat stubble. The Quicksand test was planted in conventionally tilled seedbeds following a cover crop of rye. Fertilizer was applied as indicated by soil tests.

All test areas were treated with herbicide(s) and supplemented by post-emergence cultivation and/or herbicide when necessary. Force was applied in the row at planting to control corn root-worms. Table 3 shows the specific cultural treatment for each location and includes notes about the growing season.

Locations of the 2003 Hybrid Corn Performance Test

E=Early, M=Medium, L=Late, W=White

Experimental Design and Mean Comparisons

Each hybrid was grown in three replications at each location to sample uncontrollable variability of soil types, fertility, and other factors. Annual mean yields presented in the tables are averages of three replications at the test site, while two-year and three-year means are averages of six and nine replications, respectively. A randomized complete block (RCB) design was used for each maturity group test at each location.

Small differences in yield are usually of little importance. The yield of two varieties at a single location may differ because of chance factors (difference in soil characteristics, fertility, or availability of moisture) even though the inherent yielding ability is the same. To decide if an observed yield difference is real, use the LSD (least significant difference) provided at the bottom of the tables. If the difference in yield is greater than the LSD value, you may be reasonably certain that the entries actually do differ in yield ability. Consider the following example:

Variety	Yield (bu/ac)
A	135
B	125
C	110

$$\text{LSD (0.10)} = 12.0$$

The deviation between variety A and variety B is 10 bu/ac ($135-125=10$). The difference is smaller than the LSD (12 bu/ac). We can thus infer with reasonable confidence that varieties A and B have the same yield in this test. However, the difference between varieties A and C is 25 bu/ac ($135-110=25$), which is larger than the LSD (12 bu/ac). Therefore, we can infer that variety A yielded more than variety C in this test. "N.S." in the tables indicates that no statistically significant differences were determined. The LSD is calculated for an alpha level of 0.10. For your convenience, an asterisk has been placed alongside those yield means that are not significantly different from the highest yield mean in that column. This comparison indicates that those means followed by an asterisk do not differ by more than one LSD.

The C.V. expresses the amount of variation as a percentage of the hybrid mean. A low C.V. indicates little unexplained variation and more precise results.

Planting

All plots were planted with a John Deere vacuum, two-row, no-till planter modified for small plot work. The planter boxes were replaced by modified planting cones that allowed placement of a specified number of kernels per plot. Each plot consisted of two rows 30 inches apart and 22 feet long. Each plot was planted with 40 seeds/row. When seedlings were 12 to 18 inches tall, the plots were thinned to 33 plants/row, which equals a plant population of 26,000 plants/acre.

Harvesting

All plots were harvested with a Massey Ferguson MF 8-XP two-row corn combine. Both rows of each two-row plot were picked and shelled. The grain weight and moisture content of each plot was measured with an electronic scale and moisture meter mounted on the combine. Data from each test location were temporarily stored in a portable data logging device prior to transfer to a computer at Lexington. Yields were calculated for grain at 56 pounds per bushel and adjusted to 15.5% moisture. Test weight also was provided by the electronic weighing device. The test weight reported in each annual table for any hybrid is not corrected for harvest moisture and is reported at the moisture content for that hybrid listed in that table. Dropped ears were not gleaned from the plots.

The total number of lodged plants was recorded immediately prior to harvest. Also at harvest, selected plots were observed to indicate apparent European corn borer damage by counting the number of broken tops per plot (personal communication, Dr. Ric Bessin, Department of Entomology, University of Kentucky). Corn borer damage was most severe at the Lewisport location and was minor at the other locations. In general, Bt hybrids had less apparent corn borer damage than non-Bt hybrids.

Chemical Analysis of the Early, Medium, and Late Tests

Chemical composition was measured from one replication of each early, medium-, late-, and white-maturity test at each location. These samples were analyzed by the Kentucky Grain Quality Laboratory at Lexington¹ using Near Infrared Reflection Spectroscopy (NIRS). The NIRS analysis provided evaluation of protein, starch, and oil and is presented in Table 8 for grain at 0% moisture.

Since grain used in feed rations contains some moisture, the composition variables provided in Tables 8 and 16 should possibly be used at a moisture content that is different from the 0% shown in Tables 8 and 16. To convert to a suitable moisture content, for example 15% moisture, multiply the values in Tables 8 or 16 by 0.85. For any other moisture content, multiply the values by $(100 - \% \text{ moisture})/100$.

High Oil Tests

High oil hybrid blends (TC High Oil Blend®) were tested at three locations. The yield and composition information will be useful to farmers feeding high oil (high energy) grain to livestock and to those participating in the high oil, value-added grain market. The tests had nine entries at three locations with three replications per location. The three-location average yield data are available in Table 16D. A 20- to 25-plant, hand-pollinated sample from each replication of the Lexington test was analyzed for chemical composition. The grain was analyzed by Wei Chen in the Grain Quality Laboratory, located in the Biosystems and Agricultural Engineering Building, under the direction of Dr. Michael Montross, using NIRS.

The chemical composition values presented in Table 16G are given for grain at 0% moisture.

¹ The Grain Quality Laboratory is a service provided by the University of Kentucky Agronomy Department with funding from the Kentucky Corn Growers Association.

Hybrid Comparisons

The Kentucky Hybrid Corn Performance Test was grouped into four tests: early, medium-, and late-maturities and white hybrids. These divisions provide evaluations of the four hybrid groups without competition biases. Although the divisions reduce biases, it does not allow for comparisons across maturity groups. For example, a hybrid in the early test cannot be compared to a hybrid in the late test. The four tests were grown at all seven locations for a total of 28 tests.

The early maturity hybrid group in Table 4E and all subsequent "E" tables are those hybrids rated by the parent seed company to mature in 112 days or earlier.

The medium-maturity hybrid group in Table 4M and all subsequent "M" tables include those hybrids rated by the parent seed company to mature in 113-117 days.

The late-maturity hybrid group in Table 4L and all subsequent "L" tables include those hybrids rated by the parent seed company to mature in 118 days or later.

The white hybrid group in Table 4W and all subsequent "W" Tables include those hybrids rated by the parent seed company to mature in 112-118 days.

The open-pedigree hybrids were included in each early, medium, and late test, respectively, to provide an internal evaluation of hybrid maturity. The seed of these hybrids was obtained from Illinois Foundation Seeds, Inc., at Champaign, Illinois.

Notes about the 2003 growing season follow Table 3.

Note

All Western Kentucky locations were observed for potential problems during the months of June, July, and August. Eastern Kentucky locations were checked on several occasions during the growing season.

Acknowledgments

The authors sincerely appreciate the efforts of the Kentucky Corn Growers Association in helping us upgrade plot equipment. A Massey Ferguson MF 8-XP combine was leased to the corn project at minimal cost by the Kentucky Corn Promotion Council of the Kentucky Corn Growers Association. This combine contributed to improved accuracy of the data.

The authors are also grateful to Dr. Michael Montross, Wei Chen (research analyst) and the Kentucky Corn Growers Association for the Grain Quality Laboratory, which processed more than 900 grain samples. The authors are also grateful to the following farmer-cooperators who not only provided land for testing but helped with the tests throughout the growing season: Rob and Robert Garrigan and family of Fulton, Jim Shelton of Hopkinsville, Steve Sheffer and family of Hodgenville and Steve and Shelby Emmick and family of Lewisport.

The authors also acknowledge the statistical and programming support of Dr. Paul L. Cornelius and Danny Walls of the UK Agronomy Department.

Additional acknowledgments are made to the following people who helped conduct this year's performance test.

- Richard C. Green, Research Technician, Department of Agronomy, Lexington
- Dr. Morris J. Bitzer, Research Specialist in Grain Crops, Lexington
- Dr. James Herbek, Extension Specialist in Grain Crops, Research and Extension Center, Princeton
- Donnie Davis, Superintendent, and Royce Burchett, Farm Manager, Research and Education Center, Princeton
- David Ditsch, Superintendent, and William Bowling, Farm Manager, Robinson Substation, Quicksand
- Dennis Duross, Extension Communications Specialist, and Terri McLean, Editor, Agricultural Communications, Lexington
- Cam Kenimer, Extension Agent, Fulton County
- James Stone, Extension Agent, Christian County
- Diane Perkins, Extension Agent, Hancock County
- David Harrison, Extension Agent, LaRue County

NOTES on the 2003 GROWING SEASON

FULTON: There was very little weed or corn borer pressure at this location.

PRINCETON: Weed control of the wheat cover crop was poor and resulted in erratic yields in the early and medium tests. As a result, those two tests were not included in this report.

HOPKINSVILLE: Southwestern corn borer damage was minor (<10%).

LEWISPORT: A replanting occurred on June 2 because of water damage to the initial planting. There were some weed problems and high levels of both European and Southwestern corn borer damage (>50%). Grain in the medium, late, and white tests was too moist (>30%) for harvest at the time of publication and the data is not included in this report.

HODGENVILLE: There were no disease problems but some damage due to Southwestern corn borer (10%).

LEXINGTON: There were no pest problems at this location.

QUICKSAND: This location had minimal damage due to Southwestern corn borer (<15%).
